

APA Report

- A two way between - subjects

ANOVA was conducted to examine

the effects of fertilizer formulation

(Blend X, Blend Y, Blend Z) and

crop type (wheat, corn, soy, rice)

on yield. The results revealed a

significant main effect of

fertilizer, $F(2, 48) = 9.93, P < .001$

indicating that overall yields varied

significantly across the three

formulations. the main effect of

crop type was not significant,

$F(3, 48) = 2.57, P = .065$

Most importantly, a significant interaction between fertilizer and crop type was found, $F(6, 48) = 2.35$, $p = .046$. Because the interaction is significant, the null hypothesis - stating there is no significant interaction effect - is rejected. These findings suggest that the effectiveness of a specific fertilizer blend is contingent upon the type of crop being treated. Specifically, agricultural

yield is optimized when
the fertilizer formulation
is matched to the specific
biological requirements of the
crop.

since the interaction is significant, the
data suggest you should recommend
specific blends for specific crops.
