REMARKS:

The mixed-design analysis of variance revealed a statistically significant three-way interaction between gender, looks, and personality, indicating that the influence of a partner's character on dating preferences is simultaneously dependent on both their physical appearance and the gender of the person evaluating them. Follow-up analysis of the simple two-way interactions demonstrated that for the first group, physical attractiveness acted as the primary driver of high ratings; in this group, being highly attractive served to protect a person from the negative impact of having no charisma. Conversely, the second group prioritized personality above all else, awarding high scores to charismatic individuals even if they were physically unattractive, while heavily penalizing those who were physically attractive but lacked any charisma. While the individual effects of looks and personality were both found to be highly influential across the entire study, the overall effect of gender itself was not significant, suggesting that while the groups used different mental criteria to judge partners, their average ratings were remarkably similar. Preliminary checks confirmed that the data was suitable for this analysis, as the spread of the scores was consistent across groups and the ratings followed a generally normal distribution.
